

> WHAT IS EL NIÑO

El Niño is a shift in ocean temperatures that happens every few years.

Warm water in the Pacific Ocean shifts east. This changes wind patterns and rainfall across Australia. It's not a disaster, it's just the climate doing what it does.

Every El Niño is different. Some years are hotter and drier. Some years bring rain. That's why the forecast matters more than the label.

> EL NIÑO 2026

El Niño is here. But this one isn't following the textbook.

So what does that mean for summer?

Australia's weather is being influenced by more than one climate driver. Here's what we know - and what it could mean for your home.

> FIRST, THE BASICS

El Niño doesn't mean everywhere gets hotter.

It changes the odds.

El Niño typically shifts Australia's climate towards warmer daytime temperatures and drier conditions across parts of the country.

But every El Niño is different.

> THIS YEAR IS DIFFERENT

The Pacific is only part of the story.

El Niño would normally push parts of Australia towards drier conditions.

But other climate influences - including unusually warm surrounding oceans - can change how that pattern plays out.

That's why “El Niño = hot and dry” is too simple.

> WHAT IT MEANS AT HOME

The forecast isn't a guarantee. It's a reason to plan.

Warmer-than-average conditions are favoured across significant parts of Australia this spring.

If you're already thinking about:

- > servicing an existing system
- > replacing an ageing system
- > installing air conditioning before summer

spring gives you time to make that decision properly.

Before you actually need it.
